Harry Styles at MSG — Secondary-Market Pricing Report (as of Oct 1, 2026)

Oct 1, 2026 · Yicheng

Executive summary

For the 14 remaining shows (Oct 2–31) the base case is **pass**: no show and no section is trading more than 10% below fair value, while a resale round trip needs roughly 29% below fair value to pay. Oct 7 and Oct 9 are trading 12–15% **above** fair value — a time to sell inventory, not to buy.

- **The market.** 30 shows, one venue, one seat map: effectively 30 expiry dates on one underlying. Data: 38,570 SeatData sales (Aug–Sep 29) plus 5 refreshed exports (6,727 rows) through the evening of Oct 1; fees measured from 16 real checkouts. All prices in this report are base prices before fees.
- **The model.** A fair-value surface: log price = section + row + quantity + time-to-show + show + calendar. Daily replay Sep 1–27: mean error $62 vs $90 for a comparable-sales benchmark (−32%). Pre-registered Sep 30 window: median error 7.8%. 232 sales since the coefficient freeze: median error 11%, median actual/model 1.03.
- **What the market does.** Prices fall ~21% from 14 days out to 1 day out. Later shows are cheaper (~18% per 10 shows), Wednesdays −4%, Saturdays +14%, Halloween finale +83%. Sections 107/117 carry a 42–52% premium over end sections; row 3 is 47% above row 15; single tickets clear ~18% below pairs. Volume concentrates in the last 2–3 days without a price collapse — the only discount is in the final 3 hours. Three-day momentum does not exist.
- **Where the remaining shows stand (Oct 1).** Oct 2 fair (−2%), Oct 3 fair, Oct 7 rich (+15%), Oct 9 rich (+12%). The other 10 shows were at fair value as of Sep 29 and need a data refresh. The Halloween premium is already in the price.
- **Recommendation.** Pass on new purchases; maximum buy price = 0.71 × model when the buying channel charges a buyer fee (SeatGeek, StubHub, Ticketmaster primary) or 0.82 × model when it does not; list any Oct 7 / Oct 9 inventory at model price now; never hold into show day.

The market and the data

Harry Styles plays 30 shows at Madison Square Garden, every Wednesday, Friday and Saturday from Aug 26 to Oct 31, 2026 — his only US dates this year. Same artist, same building, same seat map; only the date changes. That makes the residency a term structure rather than 30 separate events: a Wednesday vs Saturday is a calendar spread, Oct 30–31 (“Harryween” and the finale) is a seasonal premium, and the Oct 10–31 block went on sale five days after the rest. As of Oct 1, 16 shows are done and 14 remain.

Item	Detail
Sales data	SeatData transaction records: timestamp, section, row, quantity, base price (before fees). 38,570 rows across all 30 shows through Sep 29 22:36 UTC; 5 shows re-exported Oct 1

Item	Detail
	(6,727 rows, latest record 6:44 pm ET Oct 1)
Scope of the model	100 Level, numbered sections 101–120, rows 3–22, sales before show start. This is the deepest, most comparable segment; pit, 200/300 Level and bridges are excluded
Quotes	1,118 listing observations across SeatGeek, Gametime and TickPick from screenshots; 16 SeatGeek checkouts used to measure the buyer fee
Comparison residency	Backstreet Boys at Sphere (21 shows) as a replication check
Known gaps	Official face values not collected; Oct 1 export is partial-day; SeatData backfills late sales for several hours

Two things the data cannot see: primary-market inventory still unsold at Ticketmaster (the hard cap on resale prices), and the seller's channel fees, which decide the buy threshold in the next sections.

The pricing model

The model gives a fair value for any 100 Level seat at any time before the show: it is a reference price, not a buy signal. It is a regression of the log of the base sale price on six components, refit every day on the data available that morning (coefficients in the appendix).

Component	What it captures	Size
Section	Where the seat sits around the bowl	117: +52%, 107: +42%, 116/118: +28–30%, 106/108: +21–24%; ends (101–104, 110–114, 120) 0–5%
Row	Distance from the floor, plus a front-row kicker for rows 3–6	−13% per 10 rows back; row 3 is +47% vs row 15
Quantity	How many tickets sold together	single −12%, pair +7%, 3–4 +16%, 5+ +25% (vs unknown)
Time to show	A piecewise curve in log(days)	30 d: 1.18, 14 d: 1.00, 7 d: 0.91, 2 d: 0.83, 1 d: 0.79 (ratios to the 14-day level)
Show	Each date's level vs the Aug 26 opener	Wednesdays −18 to −29%, Fridays −4 to −15%, Saturdays −6 to +6%, Oct 30 +27%, Oct 31 +83%
Calendar	Market-wide drift	−6.7% per two weeks in-sample; frozen at zero for forecasts

Fit: Huber-type robust ridge regression (observations with log residuals over 0.25 are down-weighted), 90-day training window, sample weights decaying with a 14-day half-life so the coefficients reflect the last two weeks of trading. The forecast version used in this report is the Sep 29 fit, frozen so that everything after it is a true out-of-sample test.

Worked example — Oct 10 (Saturday), section 107, row 10, a pair, 7 days before the show: 5.509 + 0.071 (row) + 0.163 (time) + 0.353 (section) + 0.062 (section × row) + 0.057 (show) + 0.072 (pair) = 6.287 → **$537** base. Buyer pays about $615 after a 14.6% fee; a seller nets about $460–485 after a 10–15% channel fee.

Accuracy and validation

The model has been tested three ways and its error is consistently 8–12% of price, roughly a third better than pricing off recent comparable sales. The two tests after the Sep 29 freeze are genuine out-of-sample results: the predictions existed before the sales happened.

Test	Sample	Model error	Benchmark	Note
Daily replay, Sep 1–27	4,955 sales; each day priced with only prior data	MAE $61.6; median error 11.8%	Comparable-sales median: MAE $90.3; 18.3%	Model beat the benchmark on 27 of 27 days; 80% prediction intervals covered 81% of Sep 21–27 sales
Pre-registered window: Sep 30 show, Sep 30 00:00 to showtime	35 sales	MAE $36.6; median error 7.8%	—	Coefficients frozen Sep 29 22:36 UTC before the window opened; actual prices ran 5% above model
All sales after the freeze, 5 shows	232 sales through Oct 1 pm	MAE $40.9; median error 11.0%	—	Median actual/model 1.03; 19% of sales below 0.9 × model, 33% above 1.1 × model

By segment the error is flat: premium sections 9.8%, other sections 11.2%; rows 7–10 7.9%, rows 11–22 10–11%, rows 3–6 18% (few, expensive seats); pairs 7.0%, singles 11.7%. No segment is systematically mispriced.

One result cuts the other way and belongs here: the **change** in price over the next three days is not predictable. A “no change” forecast beat both candidate models (MAE 7.25 vs 8.13 and 8.15 index points). The surface prices the cross-section well; the time dimension is close to a random walk at a three-day horizon.

Finding 1 — Prices decay into the show

A 100 Level seat loses about a fifth of its value between 14 days out and the day before the show, and most of that loss lands in the final two days.

Days before show	Price vs 14-day level
30	1.18
14	1.00
7	0.91
4	0.89
2	0.83
1	0.79
0 (showtime)	0.78

The same pattern shows in the raw data without the model: for the first 15 shows, 100 Level sales in the last 12 hours cleared 28% below the 7–30 day level, or 12% below after controlling for the market-wide drift across calendar weeks. The decline is steady, not a cliff — there is no late rebound.

Why: a ticket is a perishable asset with a hard expiry. As the show approaches the seller's chance of finding another buyer shrinks, so the price they will accept falls (the same mechanism documented for MLB tickets on StubHub in the academic literature). Buyers know this and wait.

Implication: holding inventory into show week is a losing position by construction. Anything bought must be listed immediately at fair value; the model's curve is the clock.

Finding 2 — Later shows are cheaper; the weekday and Halloween set the rest

Comparable 100 Level prices fall about 18% for every 10 shows further into the residency (95% CI −26% to −9%, measured 7–14 days before each show), after adjusting for seat and weekday. On top of that, Saturdays trade 14% above the average and Wednesdays 4% below; the Halloween shows are the only dates priced above the residency's start.

Show group	Level vs Aug 26 opener	Shows
Wednesdays	−18% to −29%	Sep 30 −22, Oct 7 −25, Oct 14 −22, Oct 21 −24, Oct 28 −18
Fridays	−4% to −15%	Oct 2 −13, Oct 9 −4, Oct 16 −4, Oct 23 −11
Saturdays	−6% to +6%	Oct 3 +4, Oct 10 +6, Oct 17 +6, Oct 24 −6
Halloween	+27% / +83%	Oct 30 +27, Oct 31 +83 (finale)

Why: 30 shows × roughly 19,000 seats put over half a million tickets into one city. Fans bought the early dates first; sellers who bought later dates face thinner demand and more competing inventory. A replication on the Backstreet Boys Sphere residency (21 shows) shows the same direction, −15% per 10 shows, though not statistically significant on its own.

Two caveats on identification. The effect could be show order, calendar time or the Sep 10 announcement of a 2027 tour, which cannot be separated inside one residency; adding a post-announcement control cuts the estimate to −12% with a confidence interval that crosses zero. And the Oct 7/Oct 9 data since Oct 1 suggests the Wednesday discount is narrowing (see the remaining-shows section).

Implication: for a buyer, the calendar is a bigger risk than the countdown. The same seat bought for a late-October Wednesday is worth 20–25% less than for a September Saturday, before any time decay. The Halloween premium is real but is already in the trade prices; it is an opportunity only for face-value primary inventory, if any remains.

Finding 3 — Seat structure: section, row and quantity

The centre of the long sides is the money: sections 117 and 107 sell at 52% and 42% above the end sections, and a row-3 seat sells 47% above row 15 in the same section. These effects are stable across shows and are what the model prices best (error 7–10% in these cells).

Section group	Premium vs end sections	Reading
117, 107	+52%, +42%	Centre of each long side, straight-on view of the stage
116, 118, 106, 108	+21% to +30%	Next to the centre
115, 119, 105, 109	+7% to +12%	Shoulders
101–104, 110–114, 120	0% to +5%	Ends and corners

Two refinements matter for pricing individual listings. In 107 and 117 the row slope is steeper than elsewhere — back rows in a premium section lose value faster — so a row-20 seat in 107 is worth less than its section label suggests. And quantity carries a price of its own: single tickets clear about 18% below pairs, 3–4 seat blocks sell at a 7–8% premium over pairs, 5+ at 14% over pairs.

Why: the view explains the section and row structure. Quantity is a demand effect — most buyers want two seats together, so a lone single has fewer bidders, while blocks of 3–4 are scarce and sought by groups.

Implication: a single that looks cheap is not cheap, and splitting a pair into singles destroys about 18% of value. Price every listing on its own section × row × quantity cell, not on the section average.

Finding 4 — Volume comes late, the discount comes last, and there is no momentum

Buying concentrates in the last 2–3 days before a show, but the extra volume does not push prices below fair value; the only real discount appears in the final three hours and is too small and too late to trade.

Volume. 100 Level sales recorded on Sep 30 and Oct 1 (Oct 1 partial): Oct 2 show 95, Oct 3 show 40, Oct 7 show 34, Oct 9 show 21. The Sep 30 show logged 56 sales on its own show day. In the stage-4 study of the first 15 shows the 0–7 day window was the busiest window for every show.

How the Sep 30 show cleared (actual price ÷ model price, 100 Level, rows 3–22):

Hours before showtime	Sales	Median base price	Actual ÷ model	Share below 0.9 × model
4–7 days	49	$270	0.99	18%
2–4 days	47	$253	1.00	11%
24–48 h	48	$269	1.06	10%
12–24 h	9	$269	1.11	0%
6–12 h	10	$285	1.09	0%
3–6 h	12	$270	1.07	0%
0–3 h	12	$227	0.94	42%

Show-day sales ran slightly above model until the last three hours, when the median dropped 16% and five of twelve sales went below 0.9 × model. The seats that cleared in the last 24 hours were mostly in 106, 107 and 115, at model price.

Momentum. On an index of 100 Level prices, a naive test showed strong three-day reversal ($\beta = -0.49$). It was an artefact: consecutive three-day changes share a measurement endpoint, so noise in that endpoint shows up as reversal. Splitting the endpoint cut β to −0.14 (confidence interval through zero); fully non-overlapping windows gave +0.04. Past three-day moves say nothing about the next three days.

Why: late buyers are demand, not distress, so volume rises without prices falling. Distress exists only in the final hours, among sellers with nothing left to lose. The absence of momentum means the market absorbs information quickly at the three-day horizon.

Implication: waiting for a late fire sale is not a strategy — the discount is a dozen tickets in the last three hours, mostly beyond delivery cut-offs. Entry timing based on "it has been falling" or "it is due to bounce" has no support.

Fees and the buy threshold

A ticket bought on a channel that charges a buyer fee (SeatGeek, StubHub, or Ticketmaster primary with its service fee) and sold on a resale marketplace must be found about 29% below model fair value to return 10% on capital; only a channel with no buyer fee (TickPick, broker-to-broker, our own platform) lowers the bar to 18% below fair value. The model's typical error is 11%, so listings that clear the bar are rare and usually have a reason (obstructed view, a single, the wrong ticket type).

Input	Value	Source
Buyer fee on SeatGeek	14.6% of base (range 14.25–15.03%)	16 real checkouts, Sep 2026
Seller channel fee	10–15% of sale price	Assumed; to be confirmed for our selling channel
Target return on capital	10%	Assumed

A round trip has three legs: the buyer fee on the purchase (on that leg we are the buyer — a listing at L on SeatGeek costs L × 1.146), the channel fee on the sale (the end buyer's fee goes to the platform; we receive the base price less the seller fee), and the target return. Formula: maximum buy price ÷ model price = (1 − seller fee) ÷ [(1 + target return) × (1 + buyer fee on the purchase)].

Buying channel (buyer fee)	Seller fee	Target return	Max buy price ÷ model	Discount needed
SeatGeek 14.6% (measured)	10%	10%	0.71	29%
SeatGeek 14.6%	10%	5%	0.75	25%
Ticketmaster primary (service fee ~15–20%)	10%	10%	0.68–0.71	29–32% vs face
No-buyer-fee channel (TickPick, broker-to-broker, own platform)	10%	10%	0.82	18%
No-buyer-fee channel	10%	5%	0.86	14%
No-buyer-fee channel	15%	10%	0.77	23%

Worked check at a 15% discount: a listing 15% below model bought on SeatGeek costs 0.85 × 1.146 = 0.974 × model and nets 0.90 × model when sold at model — a 7.6% loss. The same listing bought on a no-buyer-fee channel costs 0.85 and nets 0.90, a 5.9% gain. So "15% below

is enough" holds only when the buying channel charges no buyer fee and a 5% per-trade return is acceptable; which row of this table applies is the first question about our sourcing.

Why this matters more than the seat structure: every regularity in Findings 1–3 is already in the trade prices, and the round trip costs 25–30% of price. Edge can only come from listings mispriced by more than the round trip, and the data says those are a small minority — 19% of recent sales were below 0.9 × model, and only 2 of 232 below 0.7 × model.

Where the remaining 14 shows stand (Oct 1)

Nothing is cheap. The four shows with fresh data trade at or above fair value — Oct 2 slightly under (−2%), Oct 3 at fair value, Oct 7 and Oct 9 clearly above (+15% and +12%). The other ten shows were at fair value in the last week of September and need a fresh export before the meeting conclusions are extended to them.

"Fair value" here is the frozen Sep 29 model, which already contains each show's historical discount and the time-decay curve. A ratio above 1 therefore means the show has firmed relative to its own history, not that it is expensive in absolute terms: Oct 7 is still a cheap Wednesday, just less cheap than before.

Show	Level vs opener	Sales Sep 23–29	Actual ÷ model, Sep 23–29	Sales Sep 30–Oct 1	Actual ÷ model, Sep 30–Oct 1	Median base price, latest	Verdict
Fri Oct 2	−13%	103	0.97	89	0.98	$269	Fair, slightly under
Sat Oct 3	+4%	75	0.98	41	1.01	$334	Fair
Wed Oct 7	−25%	98	0.99	31	1.15	$292	Rich — sell
Fri Oct 9	−4%	46	1.01	22	1.12	$352	Rich — sell
Sat Oct 10	+6%	38	1.03	—	—	$450	Fair (as of Sep 29)
Wed Oct 14	−22%	34	1.11	—	—	$350	Slightly rich (as of Sep 29)
Fri Oct 16	−4%	30	0.93	—	—	$378	Slightly cheap (as of Sep 29)
Sat Oct 17	+6%	17	1.01	—	—	$484	Fair (as of Sep 29)
Wed Oct 21	−24%	38	0.97	—	—	$292	Fair (as of Sep 29)
Fri Oct 23	−11%	22	0.99	—	—	$367	Fair (as of Sep 29)
Sat Oct 24	−6%	37	0.98	—	—	$385	Fair (as of Sep 29)
Wed Oct 28	−18%	32	0.98	—	—	$329	Fair (as of Sep 29)
Fri Oct 30	+27%	24	0.90	—	—	$546	Slightly cheap (as of Sep 29); premium already priced
Sat Oct 31	+83%	16	1.01	—	—	$806	Fair; premium already priced

Reading the Oct 7 / Oct 9 move: their ratio rose from about 0.95 a week ago to 1.15–1.21 on Sep 30 and Oct 1. The model's historical Wednesday discount for Oct 7 is −25%; the market is now pricing closer to −13%. Samples are small (31 and 22 sales) but the direction held on consecutive days. Plausible causes: late demand spilling from the sold-down Oct 2–3 inventory, or thinner supply for the first week of October; neither can be confirmed without listing counts.

The "recent decline" view is not supported relative to the model. Absolute prices are falling at the pace the model expected (about −0.5% per day plus the countdown curve); they are not falling faster, and the two early-October weekday shows are firming.

Recommendation

Do not buy Harry Styles MSG inventory at current prices; sell what is held for Oct 7 and Oct 9; keep the model running as the price reference and act only when a listing clears the fee-adjusted bar.

1. **No new purchases at market.** No show or section is more than 10% under fair value; the bar for a resale-to-resale trade is 29% under. Preserving capital is the correct decision on this event.
2. **Sell Oct 7 and Oct 9 inventory now** at model price (or 5% above and work down). Both are 12–15% over fair value and, as Wednesdays and Fridays in the back half of the residency, have no structural support for the premium.
3. **Maximum buy price rule** for any listing that does appear: 0.71 × model price when the buying channel charges a buyer fee (SeatGeek, StubHub, Ticketmaster primary), 0.82 × model when it does not, assuming a 10% seller fee and a 10% target return. Price the specific cell: section × row × quantity × expected sale date.
4. **Never hold into show week.** Anything bought is listed the same day at model price; the countdown curve is the clock for markdowns, and the last-3-hour discount is not a fallback.
5. **Halloween is a primary-market question.** Oct 30/31 carry +27% / +83% premiums that are already in resale prices. If Ticketmaster still holds face-value inventory for either date, that is the only Harry Styles opportunity on the board — worth a check before each on-sale wave.
6. **Watch the Wednesday discount.** If Oct 14/21/28 also firm toward −13% rather than −25%, held inventory in those dates should be sold into the strength the same way.

What would change this view: fresh exports showing a show at 0.8 × model or below in the premium sections; evidence of face-value inventory at Ticketmaster for Oct 30–31; or a confirmed selling-channel fee well below 10%, which would raise the buy bar to roughly 0.75–0.79 × model.

Limitations and open questions

The model is a reference price for one segment of one residency; it is not a profit forecast, and five things limit how far its conclusions travel.

- **Scope.** 100 Level, rows 3–22, numbered sections only. Pit, 200/300 Level, bridges and suites are not priced. Rows 3–6 have the largest error (18%) because there are few sales at high prices.
- **One residency.** Every regularity is measured on Harry Styles at MSG; the Backstreet Boys check supports the direction of the order effect but nothing else has been replicated. The show-order effect, the calendar drift and the Sep 10 tour announcement cannot be separated inside one residency.
- **Sales only, no supply.** The data records transactions, not active listings, so listing counts, days-on-market and the probability that a given ask sells are unknown. That is the main reason the model cannot yet say *when* a listed ticket will sell at a given price.
- **No face values.** Without the primary price map, the share of resale trades clearing below face — the direct measure of broker losses — cannot be computed.
- **Fresh data covers 5 of 14 shows.** The verdicts on Oct 10–31 are as of Sep 29 and in-sample; the final-hours discount rests on 12 sales; the Oct 1 export ends at 6:44 pm.

Questions the data cannot answer and the meeting can:

- Which selling channel do we use, what is its fee, and what is the payout lag? (Sets the buy bar.)
- Is there any face-value inventory left at Ticketmaster for Oct 30–31, and how do we see primary releases coming?
- Which event types made money last year and which lost — are residencies like this one a category we touch at all?
- What was the typical holding period on winning trades: bought to flip the same day, or held into show week?
- Can we get listing-level data (active listings, price changes, delistings) so the model can price time-to-sale, not just price?

Appendix

A. Forecast grid for the remaining shows

Frozen Sep 29 model, base price in USD before fees, a pair of tickets, calendar drift held at zero. Columns are four reference seats at 7 days and 1 day before the show. Any other cell follows from the formula in B.

Show	107 row 10, T−7	107 row 10, T−1	117 row 15, T−7	117 row 15, T−1	112 row 15, T−7	112 row 15, T−1	101 row 20, T−7	101 row 20, T−1
Fri Oct 2	$443	$383	$414	$358	$276	$238	$254	$219
Sat Oct 3	$526	$455	$492	$425	$328	$283	$302	$261
Wed Oct 7	$379	$327	$355	$306	$236	$204	$217	$188
Fri Oct 9	$488	$421	$456	$394	$304	$262	$280	$242
Sat Oct 10	$537	$464	$503	$434	$334	$289	$308	$266
Wed Oct 14	$397	$343	$372	$321	$247	$214	$228	$197
Fri Oct 16	$486	$419	$454	$392	$302	$261	$279	$241
Sat Oct 17	$540	$466	$505	$436	$336	$290	$310	$267
Wed Oct 21	$388	$335	$363	$313	$241	$208	$222	$192

Show	107 row 10, T−7	107 row 10, T−1	117 row 15, T−7	117 row 15, T−1	112 row 15, T−7	112 row 15, T−1	101 row 20, T−7	101 row 20, T−1
Fri Oct 23	$450	$388	$420	$363	$280	$242	$258	$223
Sat Oct 24	$477	$412	$446	$385	$297	$256	$274	$236
Wed Oct 28	$417	$360	$390	$337	$260	$224	$239	$207
Fri Oct 30	$643	$555	$602	$519	$400	$346	$369	$319
Sat Oct 31	$931	$803	$870	$751	$579	$500	$534	$461

If the in-sample calendar drift (−6.7% per two weeks) is extrapolated instead of frozen, the Oct 31 figures become $822 and $689; the gap between the two assumptions is the honest uncertainty on late-October levels.

B. Formula and coefficients

$$\ln P = 5.509 - 0.1413 \times (r - 15)/10 + 0.215 \times \max(6 - r, 0)/3 + f(u) - 0.0692 \times (t - t_0)/14 \text{ days} + S(\text{section}) + T(\text{section}) \times (r - 15)/10 + E(\text{show}) + Q(\text{quantity})$$

$$f(u) = 0.0237u + 0.1082(u - \ln 2)_+ - 0.0766(u - \ln 5)_+ + 0.0878(u - \ln 8)_+ + 0.0852(u - \ln 15)_+ - 0.1833(u - \ln 31)_+,$$ with $u = \ln(1 + \text{days to show})$ and $(x)_+ = \max(x, 0)$

where r is the row, t_0 is the freeze time (Sep 29, 22:36 UTC), S and T are the section level and section × row slope, E the show effect and Q the quantity effect; the price is exp(ln P).

Section	S (level)	T (row slope)	Section	S (level)	T (row slope)
101	0	0	111	−0.014	0.022
102	0.020	0.010	112	0.011	0.004
103	−0.001	0.033	113	−0.011	0.021
104	0.000	0.050	114	0.021	−0.002
105	0.081	0.035	115	0.117	0.010
106	0.214	−0.020	116	0.259	−0.011
107	0.353	−0.124	117	0.418	−0.171
108	0.194	−0.021	118	0.243	−0.062
109	0.074	0.053	119	0.103	0.030
110	0.029	0.031	120	0.044	0.053

Quantity Q: single −0.132, pair +0.072, three +0.147, four +0.151, five or more +0.220, unknown 0.

Show E (Aug 26 = 0): Aug 28 −0.028, Aug 29 +0.056, Sep 2 −0.097, Sep 4 −0.052, Sep 5 +0.183, Sep 9 −0.142, Sep 11 −0.151, Sep 12 −0.048, Sep 16 −0.183, Sep 18 −0.121, Sep 19 −0.050, Sep 23 −0.211, Sep 25 −0.167, Sep 26 −0.061, Sep 30 −0.216, Oct 2 −0.135, Oct 3 +0.037, Oct 7 −0.291, Oct 9 −0.040, Oct 10 +0.057, Oct 14 −0.244, Oct 16 −0.044, Oct 17 +0.062, Oct 21 −0.269, Oct 23 −0.121, Oct 24 −0.062, Oct 28 −0.196, Oct 30 +0.237, Oct 31 +0.606.

C. Data provenance

Stage	Content	Key output
01 Lead-time study	First 15 shows, 100 Level price index by time-to-show with show and calendar-week controls	Last 12 h −28% raw, −12% adjusted vs 7–30 d
02 Momentum study	3-day changes on a 100 Level index; endpoint-split and non-overlapping tests	Reversal artefact; no-change forecast wins
03 Backstreet Boys comparison	Sphere residency, 21 shows, same protocol	−15% per 10 shows, not significant
04 Later-shows study	Show-order effect with weekday control, 7–14 d and 0–7 d windows	−18% per 10 shows (CI −26% to −9%)
05 Seat groups	MSG 100 Level section groups and row bands	Grouping used by the model
06 Price model v1	Robust ridge, daily replay Sep 1–27	MAE $61.6 vs $90.3 benchmark
07 Sales update Sep 29	Reconciliation of new exports; frozen forecast model	Pre-registered Sep 30 window
08–09 Quotes	1,118 cross-platform listing observations; 16 checkouts	Buyer fee 14.6%
10 Candidate evaluation	Prototype buy-candidate workbook; parameters unconfirmed	Not used in this report
Oct 1 refresh	5 re-exported shows, 6,727 rows	232 out-of-sample sales scored; Sep 30 clearing profile
